

1. What is Python?

Python is a high-level, interpreted, object-oriented programming language. High-level means it is easy for humans to read. Interpreted means code runs line by line without compilation. It is used in web development, automation, data science, artificial intelligence, and machine learning.

Example: `print('Hello, World!')`

2. What is the difference between a List and a Tuple?

A List is mutable, meaning you can add, remove, or modify elements. A Tuple is immutable, meaning its elements cannot be changed after creation. Lists use square brackets `[]`, while tuples use parentheses `()`.

3. What are Python Variables?

Variables are names used to store data in memory. You do not need to declare a data type in Python. Example: `name='Bhagya', age=20`.

4. What is the difference between `==` and `is`?

`==` checks whether two objects have the same value. `is` checks whether two variables refer to the exact same object in memory.

5. What is a Function in Python?

A function is a reusable block of code that performs a specific task. Functions improve code reusability and reduce repetition. They are created using the `'def'` keyword and can return a result using `'return'`.
